#### ABSTRACT

Reported are manpower data needed by those engaged in science and engineering policy activities. The information is collected from scientists and engineers themselves. The basis of this report is the first survey, in a biennial series, of the Doctoral Roster of Scientists and Engineers, conducted for the National Science Foundation by the Commission on Human Resources of the National Academy of Sciences. Surveys of the Doctoral Roster constitute the data collection mechanism. The main article includes information related to doctoral scientists and engineers in private industry in 1973. Descriptive, tabulated and graphic charts are presented showing such information on the distribution of the doctoral scientists as related to totals, by employment, by field and primary work activity and by those engaged in research and development. Employment characteristics within various sectors of the economy are described. In the appendices such topics as technical note, definitions and detailed statistical tables are presented. (EB)

Documents acquired by ERIC include many informal unpublished \* materials not available from other sources. ERIC makes every effort \* \* to obtain the best copy available. ### **Doctoral Scientists and** Engineers in Private Industry, 1973

#### Introduction

Recently, considerable attention has been focused on supply and demand considerations affecting the labor market for doctoral scientits and engineers in the United States over the next 10 to 15 years. Although there are variations among specific forecasts and projections with respect to the details of supply and demand imbalances, there is general agreement that employment patterns of doctoral scientists and engineers will undergo significant changes during the next decade. These changes will be due in some measure to a projected slow growth in R&D funding which will result in a lower growth rate in the demand for personnel with advanced R&D capabilities, the traditional strengths of Ph.D. scientists and engineers. Thus, doctorate-level scientists and engineers, particularly those newly entering the job market, will be

influenced to consider nontraditional job opportunities. At the s ne time, it is expected that projected decreases in the number of science and engineering (S/E) enrollments in educational institutions will result in a shift from academic to nonacademic employment. If such a shift is realized in the future, business and industry, the principal center of nonacademic employment of doctoral scientists and engineers, will assume increasing importance in the future utilization of this important human resource in the Nation's scientific enterprise. Thus, it is prudent to understand the characteristics of the doctoral scientists and engineers who are presently employed in the industrial sector of the U.S. economy. The following presentation is directed toward this end.

#### 1973 Labor Force of Doctoral Scientists and Engineers

The population of doctoral scientists and engineers in the United States in the spring of 1973 was 244,900. Slightly more than 6 percent of this population were not seeking employment, gave no report of their employment status, were retired, or otherwise not in the labor force. Thus, the labor force numbered

This publication evolves out of the National Science Foundation's Manpower Characteristics' System which was established to provide manpower data needed by many individuals and groups, particularly those engaged in science and engineering policy activities. A characteristic feature of the System is that information is collected from individual scientists and engineers rather than from other sources; e.g., employers, professional societies, etc. Consequently, considerable information on personal and professional characteristics can be obtained which is otherwise not available.

The basis of this report is the first survey, in a biennial series, of the Doctoral Roster of Scientists and Engineers, conducted for the National Science Foundation by the Commission on Human Resources of the National Academy of Sciences. Surveys of the Doctoral Roster constitute the data collection mechanism for one element of the Manpower Characteristics System which, when combined with other elements (i.e., the National Sample of Scientists and Engineers and Surveys of New Entrants to Science and Engineering) provide information on the magnitude and characteristics of the Nation's scientific and engineering human resources.

(Prepared in the Manpower Characteristics Studies Group, Division of Science Resources Studies)

229,400. including approximately 2,600 individuals who were not employed and seeking employment, a giving rise to an unemployment rate of 1.2 percent.

At that time, the employed labor force of doctoral scientists and enginec,s numbered 226,800. Educational institutions provided the largest sources of employment accounting for almost three-fifths (58 percent) of the total employed. Of the remaining individuals, over one-half were employed by business and industry and slightly less than one-fifth by the Federal Government. The remaining individuals in the employed doctoral S/E labor force, numbering about 26,000, were-distributed more or less evenly among other employers. Thus, while nonacademic employment encompassed a variety of employment settings, business and industry provided the principal source of such employment (chart 1).

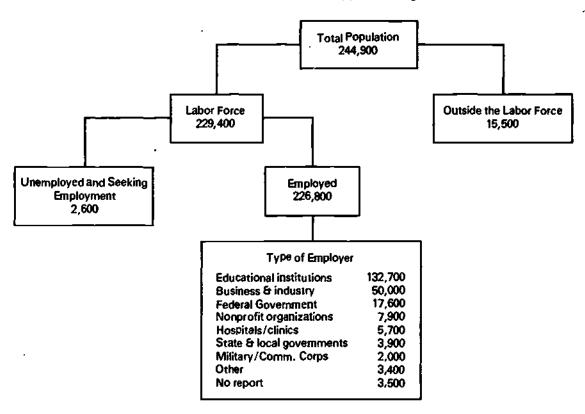

#### General Characteristics

What are the characteristics of the industrially employed group and how do they differ from those employed elsewhere?

In 1973 the great majority of doctoral scientists and engineers in private industry were white males who were employed full time in S/E-related positions. Of the 50,000 doctoral employees of industry, less than 6 percent held positions not related to science and engineering and only 2 percent were employed on less than a full-time basis. Almost three-fourths were physical scientists and engineers while about the same proportion indicated the performance or management of research and development to be their primary work activity although the extent of involvement in R&D activities was considerably less in some fields (charts 2 and 3 and table B-1).

In 1973, doctoral scientists in industry numbered 32,700, an increase of 17 percent over 1970 and 56 percent over 1966, an average annual increase of about 7 percent. In 1966 and 1970, the proportion of physical scientists in the doctorate-holding industrial labor force of scientists remained stable at about 70 percent. In 1973, however, doctorate-holding physical scientists comprised less than 60 percent of the Ph.D. scientists in industry. The relative decline in the number of physical scientists was in contrast with a general

Chert 3. Distribution of doctoral scientists and engineers in business and industry, by field and primary work scivity: 1973

increase in most other fields, notably, among life scientists, who increased in number from less than 2,000 in 1966 to almost 7,000 in 1973, an average annual increase of about 20 percent (chart 4).

Of the 50,000 Ph.D. scientists and engineers in private industry, almost one-half cited the performance (excluding management) of research and development as their primary work activity. More than one-half of this group were engaged primarily in applied

Chart 4. Doctoral scientists employed in business and industry: 1986, 1970, and 1973

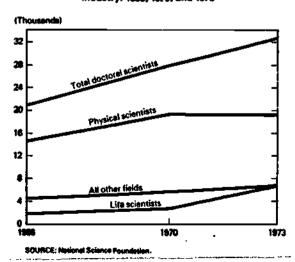

Chart 5. Distribution of doctoral scientists and engineers in business and industry engaged in R&D, by field and character of work: 1973

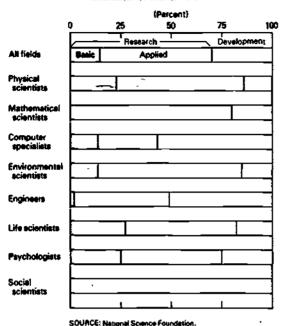

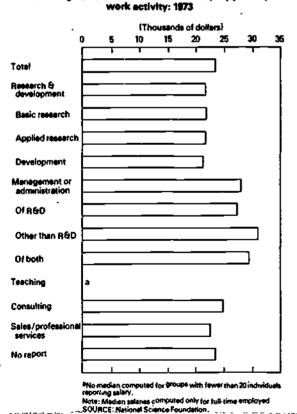

Chart 6. Median annual salaries of doctoral scientists and engineers in business and industry, by primary

research. Applied research was, in fact, the dominant R&D activity among industrial doctorate holders in all fields except in the case of computer specialists and engineers who were more heavily involved in development activities. Generally, the performance of basic research assumed a subordinate role in the work of doctoral scientists and engineers engaged in industrial R&D activities. More physical scientists and life scientists, however, were occupied with basic research than with development and two other groups (environmental scientists and psychologists) had approximately the same number working in basic research as there were in development (chart 5).

Salaries of doctoral scientists and engineers in industry were 12 percent higher than the overall median salary of \$20,900, although there were substantial differences among industrially employed groups (table B-4). Considered solely by field, for example, economists, the highest paid, reported salaries 31 percent higher than the industrywide median of \$23,400, and 38 percent higher than the salaries of industrially employed agricultural scientists, the lowest paid.

Substantial differences in salaries were also reported by individuals engaged in various work activities (chart 6). As a group, individuals engaged in the performance of research and development were the lowest paid; managers or administrators the highest. Only small differences in the salaries of basic researchers, applied researchers, and developers were noted. R&D managers or administrators, however, were paid substantially less (\$3,700 per year) than managers or administrators in non-R&D activities.

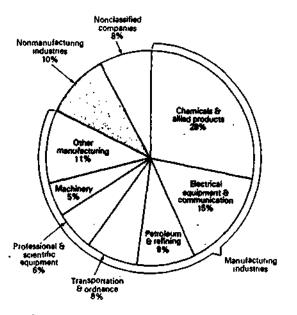

### Employment Characteristics Within Industry Groups

In 1973 manufacturing organizations employed four-fifths of the doctoral scientists and engineers in business and industry. Six industrial manufacturing groups!—chemicals and allied products, electrical equipment and communication, petroleum and refining, transportation and ordnance, professional and scientific equipment, and machinery—employed almost seven-eighths of the doctoral scientists and engineers in manufacturing industries and over two-thirds of the total number in industrial employment. Nonmanufacturing industries and nonclassified companies accounted for the remainder of those industrially employed (chart 7 and tables B-2 and B-3).

<sup>1</sup> For definition of industry groups, see technical notes.

Chart 7. Distribution of doctoral scientists and engineers in business end industry, by industry group: 1373

SOURCE National Science Foundation.

The demand for Ph.D. scientists and engineers in manufacturing industries is not surprising since these industries are considered to be highly "R&D intensive." Yet there was found to be a considerable degree of variability in this demand even among the highly R&D intensive industries. The chemical industry, for example, provided the largest relative source of employment for Ph.D. scientists and engineers who numbered 13.2 per 1,000 employees, a ratio about eight times higher than that for the machinery industry, in spite of the fact that both of these industries devoted about the same percentage of net sales to research and development. The petroleum and refining industry, on the other hand, devoted a smaller percentage of net sales to research and development, yet had a large Ph.D.-to-employee-ratio (8.5 to 1,000—table 1).

TABLE 1.—MEASURES OF RESEARCH AND DEVELOPMENT AND PH.D. INTENSIVENESS: 1973

Electrical equipment and communication	71	30
Petroleum and refining	7	8.5
Transportation and ordinanca	67	1.7
Professional and scientific equipment	56	5.8
Machinery	38	1.6
Other manufacturing	7	.9

SOURCE: National Science Foundation

Considered by industry group, only small differences in salary are noted, although doctoral scientists and engineers in nonclassified companies, reported salaries 9 percent higher than the industrywide median. Differences in salaries, by primary work activity, were considerably greater. In general, salary patterns within industry groups, however, did not differ substantially from the overall pattern. Thus, relatively small differences were noted in the salaries of basic researchers, applied researchers, and developers; R&D managers or administrators were paid less than managers or administrators of non-R&D activities (table 2).

Chemicals and allied products—The chemical industry employed the largest number of doctoral scientists and engineers in the private sector, accounting for 35 percent of those in manufacturing activities and over 28 percent of the total in industrial employment. Although chemists comprised the largest single field (58 percent) in this industry, engineers and biological and medical scientists collectively accounted for an additional 35 percent. The performance or management of R&D was cited as the primary work activity by 75 percent of the doctorate holders in this industry as compared with 71 percent among all industrially employed. This increase may be accounted for by the more significant role which basic research assumed in this industry; 11 percent of those in the chemical industry were engaged primarily in basic research as compared with a level of 7 percent in all of private industry.

Electrical equipment and communication—About three-fifths of the doctorate holders in this industry were engineers, who with physical scientists, accounted for nearly seven-eighths of the total. Examination by primary work activity also reveals that seven-eights of the total were primarily engaged in the performance or management of research and development. Only 9 percent of those engaged in R&D performance were in basic research as compared with a level of 15 percent, industrywide.

Petroleum and refining—Physical scientists and engineers, representing three-fourths of the doctoral scientists and engineers in private industry in 1973 also accounted for three-fourths of the doctorate holders in this industry group. In addition, the petroleum and refining industry was the principal employer of environmental scientists who accounted for almost one-fifth of the doctorate holders in this industry and two-fifths of the doctorate-holding environmental scientists employed in all of industry. The proportion of individuals engaged in the performance or management of research and development in this industry was commensurate with the industrywide level of 72

TABLE 2.—MEDIAN ANNUAL SALARIES OF DOCTORAL SCIENTISTS AND ENGINEERS IN BUSINESS AND INDUSTRY, BY PRIMARY WORK ACTIVITY AND INDUSTRY GROUP: 1973

SOURCE: National Science Foundation.

percent. The number of applied researchers, however, was relatively high, with two-thirds of those performing research and development engaged in this activity, as compared with about one-half industrywide.

Transportation and ordnance—Almost two-thirds of the doctorate holders in this industry group were engineers, who together with physical scientists accounted for 90 percent of the total. Research and development played a predominant role in the activities of Ph.D. scientists and engineers in this industry with 85 percent engaged primarily in R&D performance or management, 14 percentage points higher than the total industry level.

Professional and scientific equipment—Physical scientists accounted for the largest proportion in this industry, outnumbering doctoral engineers about 3 to 1. Collectively, physical scientists and engineers comprised over four-fifths of the doctorate holders in the industry. As in the case of the electrical equipment and communication and the transportation and ordnance industry groups, the proportion of those engaged in R&D performance or management was substantially higher than the total industry level.

Machinery—One-half the doctorate holders in this industry were engineers, who outnumbered physical scientists almost 2 to 1. R&D performance—the dominant activity of doctoral scientists and engineers in this industry—was accounted for, in great measure,

by the large proportion of individuals engaged in development activities; i.e., almost one-half of those in research and development as contrasted with less than one-third industrywide.

Nonmanufacturing—About two-fifths (39 percent) of the doctorate holders in nonmanufacturing industries were engineers, a level of employment higher than might be expected, considering that engineers accounted for only one-third (34 percent) of the doctorate holders in manufacturing industries. This apparent "over-representation" of engineers is offset by a smaller proportion of physical scientists who accounted for only 14 percent in nonmanufacturing industries as compared with 43 percent in manufacturing industries. The extent of involvement in R&D activities on the part of doctorate holders in nonmanufacturing industries was, however, substantially less than that of their peers elsewhere in industry; about one-half were so involved as compared with almost four-fifths in manufacturing industries. The preponderance of Ph.D. scientists and engineers in nonmanufacturing industries were employed by "service" industries, notably computer and other data processing services, medical and other health services, and miscellaneous business and other services. Highest salaries were reported by those individuals employed by finance, insurance and real estate companies (tables 3 and B-2).

### Employment Characteristics Within Various Sectors of the Economy

In what ways do the characteristics of the industrially employed group differ from those employed elsewhere?

In some respects, little variability is evident as a result of employment affiliation. With respect to age, for example, only minor differences in median age from employer to employer exist; the median age of doctoral scientists and engineers affiliated with 7 of the 10 identified employer groups (accounting for 96 percent of those employed) differed from the overall median age of 41 by one year or less. The lower median age of doctorate-holding scientists and engineers in the military service or in the Commissioned Corps may well reflect fulfillment of a service obligation on the part of young Ph.D's which was incurred as a result of educational support.

TABLE 4.—DOCTORAL SCIENTISTS AND ENGINEERS BY TYPE OF EMPLOYER, PERCENT RACIAL MINORITY, AND MEDIAN AGE: 1973

Type of employer	Total number employed	Racial minorities! (percent)	
Total employed	226,800	60	<b>a</b> 1
Business and industry ,	50.000	72	40
Educational institutions	132,700	5.9	41
Hospitals/Clinics	5.700	5.0	40
Nonprolit organizations	7.900	56	40
Federal government	17.600	3.9	42
Military/Commissioned Corps	2,000	2.1	36
State government	2.600	6.1	42
Other government	1.300	92	40
Deher	3,400	2.9	44
No report	3,500	6.9	46

<sup>&</sup>lt;sup>1</sup> Those not reporting recial status have been redistributed proportionately among racial categories.

Some differences were found among sectors in the employment of racial minorities; business and industry, for example, employed a higher proportion of racial minorities than the average for all employers, whereas the Federal establishment (encompassing both civilian and military personnel) employed a smaller proportion of racial minorities than other employers generally (table 4).

The employment of women doctoral scientists and engineers in different employment settings exhibits greater variability. Table 5 shows that women, who represented less than 1 in 10 of the employed doctoral labor force, accounted for an even smaller proportion employed by business and industry and the Federal Government. In contrast, one-fifth of the doctoral scientists and engineers employed by hospitals/clinics were women. But although the proportion of women employed in industry and the Federal Government was less than in other employment sectors, their salaries were markedly higher. The median annual salaries of women in industry and the Federal Government exceeded the overall median women's salary by 14 percent and 28 percent, respectively.

The median annual salaries of doctorate-holding men and women (combined) shows similar variability. Annual salaries about 12 percent higher than the overall median salary of \$20,900 were reported by employees of business and industry and the Federal Government. However, differentially higher salaries were evident among fields, ranging from salaries about 4 percent higher for engineers to salaries more than 33 percent higher for social scientists.

Variability is also evident in the patterns of employment, by field, among employers. From table 5 it is seen that business and industry, which accounted for less than one-quarter of the doctoral scientists and engineers in the employed labor force, provided a major source of employment for physical scientists, computer specialists, and engineers. In fact, physical scientists and engineers, representing about three-eighths of the employed labor force of doctoral scientists and engineers in 1973, accounted for almost three-fourths of those in industry as compared with about one-fourth in nonindustrial settings.

The employment of doctorate-holding physical scientists, computer specialists, and engineers in industry was in marked contrast with their peers in other fields, who were employed principally in nonindustrial settings. For the most part, educational institutions provided the largest source of such employment. Thus, almost three-fourths of the mathematical, life, and social scientists in the employed labor force of doctorate-holding scientists

Note: Detail may not add to totals because of rounding. SOURCE, National Science Foundation

Date not available.

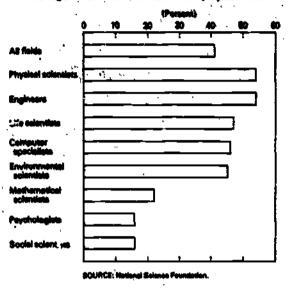

and engineers were employed by educational institutions. The employment of environmental scientists, on the other hand, was distributed more evenly among employers, although even in this case, over one-half were employed by educational institutions.

As would be expected, a very large proportion of the individuals engaged primarily in basic research and teaching were employed by educational institutions. But in other R&D areas, industry provided the dominant employment source. Thus, industry, which employed only 22 percent of the doctoral scientists and engineers in the employed labor force accounted for about one-half of those engaged primarily in applied research and in R&D management or administration, and over four-fifths of those engaged primarily in development activities (table 6).

The concentration of physical scientists and engineers in industry reported earlier, is in consonance with the pronounced involvement of those individuals in R&D activities. Chart 3 shows that about two-fifths of all employed doctoral scientists and engineers were engaged primarily in R&D activities. Among physical scientists and engineers, however, well over one-half cited the performance or management of research and development as their primary work activity. Psy-

chologists, mathematical, and social scientists, who were less involved in R&D activities, were also less extensively employed by industry.

Chart 6. Distribution of employed destoral adaptives and engineers engaged primarily in the performance or management of Rib D, by field (48 employers): 1979

### APPENDIX A Technical Notes

In the spring of 1973 the Commission on Human Resources of the National Academy of Sciences-National Research Council (NAS-NRC) conducted a survey of U.S. doctoral scientists and engineers under the sponsorship of the National Science Foundation (NSF). The population sampled consisted of individuals in the United States who either held science or engineering doctorates, or had received doctorates in other fields but were employed in science or engineering. Included in the population were individuals who received their doctorates between January 1, 1930 and June 30, 1972, inclusive. Results of the Doctoral Roster survey can be found in reports issued by NAS<sup>2</sup> and NSF.<sup>3</sup>

#### **Definitions**

The following definitions are provided to permit the effective use of data presented in this report.

Field of science and engineering—The data on field were derived from the Specialties List reproduced in table A-1. Respondents were asked to identify the specialty most closely related to their principal employment. The grouping of specialties to form fields was accomplished in conformance with the scheme presented in table A-2.

This field definition, which is used in this report, differs from the field definitions used by the Commission on Human Resources in their reports based on this survey. Care should therefore be exercised in comparing data from these sources.

Type of employer—Respondents were asked to identify, from a list of categories, the type of organization of their principal employer. Educational institutions included junior colleges. 2-year colleges, technical institutions, medical schools, 4-year colleges or universities, and elementary or secondary schools. Business or industry was listed as separate and distinct from other nonprofit employer categories which included: hospital or clinic: U.S. military service or Commissioned Corps: U.S. Government, civitian employee: State government: local or other government: international agency; and nonprofit organization, other than hospital, clinic, or educational institution.

Primary work activity—This item refers to that activity with respondents considered to be primary in relation to their position. The term "development" includes the development or design of equipment, products, systems or data; "sales/professional services" includes sales, marketing, purchasing, estimating and professional services to individuals but excludes consulting which is treated as a separate work activity; the category "other" includes report or other technical writing or editing, production, quality control, and inspection and testing.

1 This survey was based on a sample of doctoral scientists and ingineers included in the Doctoral Roster, a part of the NSF's Manpower Characteristics System

1 National Academy of Sciences, Doctoral Scientists and Engineers in the United States-1971 Profile, (Washington, D.C.), 1974.

National Science Foundation, Characteristics of Doctoral Scientists and Engineers in the United States, 1923 (NSF 75-312) (Washington, D.C. 20402: Superimendent of Documerts, U.S. Government Printing Office), 1975: Detailed Statistical Tables Characteristics of Doctoral Statistical Tables (Characteristics of Doctoral Statistics of the United States, 1973 (NSF 75-312-A) (Washington, D.C. 20550), 1975, and Reviews of Data on Science Resources, No. 24, "Work Activities of Employted Doctoral Scientists and Enginters in the U.S. Labor Force, July 1973" (NSF 75-310) (Washington, D.C. 20402 Superintendent of Documents, U.S. Government Printing Office), June 1975.

See fontmite 2.

Salaries—Salary data are derived from information regarding an individual's annual salary before deductions for income tax, social security, retirement, etc., but excluding bonuses, overtime, summer teaching or other payment for professional work. Salaries reported are median annual salaries, rounded to the nearest \$100 and computed for full-time employed civilian scientists and engineers only. Differences between calendar-year salaries (11 to 12 months) and academic-year salaries (9 to 10 months) for scientists and engineers employed in educational institutions have been accommodated by multiplying academic-year salaries by 11/9 to adjust to a calendar-year scale.

Industry groups—The classification of industrial organizations to form industry groups was accomplished in conformance with the Enterprise Standard Industrial Classification (Enterprise SIC) codes listed by the Securities and Exchange Commission. Industrial organizations cited by respondents as their principal employer were
